

Introduction (Amogh)

A job portal is a digital platform designed to connect job seekers with employers efficiently. It serves as a bridge where candidates can search, filter, and apply for relevant job openings while employers can post vacancies, manage applications, and shortlist suitable candidates. The system modernizes the recruitment process by offering streamlined workflows, easy accessibility, and organized data management.

Existing System & Problem Statement (Aditya)

Existing System:

The current recruitment landscape is fragmented and slow. Employers often rely on manual resume screenings, email-based applications, or unstructured job postings on social media. Job seekers encounter difficulties finding authentic job listings because information is scattered across multiple platforms. There is limited transparency, no centralized application tracking, and a lack of automation.

Problem Statement:

Both job seekers and employers face inefficiencies in the hiring process. Applicants struggle to access genuine opportunities and track their application status, while employers find it difficult to manage large volumes of applications. There is a need for an organized, transparent, and automated job application platform that simplifies hiring and enhances user experience.

Scope & Methodology (Vikas)

Scope:

- Employers can create, edit, and manage job postings.
- Job seekers can search, apply, and track application progress.
- Includes Applicant Tracking System (ATS) for automated screening.
- Provides communication tools for recruiters and candidates.
- Designed for scalability to support large user volumes. **Methodology:**
 1. Requirement gathering and analysis.
 2. System design including architecture and database planning.
 3. Frontend development using React for a responsive interface.
 4. Backend development with Node.js and Express for API handling.
 5. Database integration using MongoDB.
 6. Testing, deployment, and performance optimization.

Backend (Parag)

The backend of the job portal is developed using Node.js and Express. It handles core operations such as user authentication, job posting management, application submission, and ATS-based filtering. MongoDB is used to store user profiles, job listings, and application data. RESTful APIs ensure smooth communication between the frontend and database. Security measures like password hashing, role-based access, and secure session handling are implemented to ensure data protection.
